SEARCH REQUEST FORM

ME

Requester's Full Name: BEN SACKY Examiner #: 73489 Date: 11/29/05
Art Unit: 1626 Phone Number: 2-0704 Serial Number: 101776, 544
Location (Bldg/Room#): 16M5B31 (Mailbox #): 16MCL8 Results Format Preferred (circle): PAPER DISK

To ensure an efficient and quality search, please attach a copy of the cover sheet, claims, and abstract or fill out the following:

Title of Invention: Hydrogenation Catalyst

Inventors (please provide full names): Voit et al.

Earliest Priority Date: _____

Search Topic:

Please provide a detailed statement of the search topic, and describe as specifically as possible the subject matter to be searched. Include the elected species or structures, keywords, synonyms, acronyms, and registry numbers, and combine with the concept or utility of the invention. Define any terms that may have a special meaning. Give examples or relevant citations, authors, etc., if known.

For Sequence Searches Only Please include all pertinent information (parent, child, divisional, or issued patent numbers) along with the appropriate serial number.

A catalyst composition consisting of:

(a) iron or a compound based on iron or mixtures

(b) from 0.001 to 0.3% by weight based on (a) of a promoter based on 2, 3, 4 or 5 elements selected from aluminum, silicon, zirconium, titanium and vanadium,

(c) from 0 to 0.3% by weight based on (a) of a compound based on an alkaline earth metal and/or alkali metal and

(d) from 0.001 to 1% by weight based on (a) of manganese.

AB Heterogeneous catalysts for catalyzing gas-phase reactions consist of shaped high-performance catalyst particles with a diameter-height ratio of 0.5-1.0:1.0, in which the catalyst particle has a Relative Particle Size Parameter (RPSP), which is related to a pressure drop related to flow parameters, and an effective geometric catalyst surface area (GSA), in which the high-performance catalyst particle has a higher GSA for a

particular RPSP than would prior art catalyst particles. Preferably, the catalyst particle is a cylindrical ring catalyst in which the ring defines at least one standard shaped internal axial hole, such as an elliptical hole, an L-shaped hole, a rounded diamond-shaped hole, a slot hole, a pear-shaped hole, and a teardrop hole. The catalysts are especially useful in optimizing such reactions as CO₂ reforming and steam reforming of hydrocarbons, and the water gas shift reaction.

ED Entered STN: 01 May 2003

AB A catalyst mass useful for the title purpose comprises (a) Fe or a mixture, containing Fe and a Fe-based compound, whereby the Fe particles have an average middle crystallite size 1-35 nm, measured by X-ray diffraction. For example, melting 900 kg magnetite ore with 75 kg Fe powder at 1550° in the air gave a mass containing Fe 72, Mn 0.17, Al 0.08, Ca 0.03, Mg 0.05, Si 0.12, Ti 0.01% and O balance. The wustite content was 44% based on total weight, and Fe(II)/Fe(III) ratio was 1.76. The mass was comminuted, the fraction containing particles 1.5-3 mm was reduced for 72 h at 450° under H/N stream, then cooled and passivated for 24 h at <65° in N containing 1% O to give a catalyst with average size of Fe crystallites 29.5

nm.

The catalyst (239 g) was packed in a series of tubular reactors, reduced with H for 24 h at 70-340° and 72 at 340°, cooled to 107° and a stream of 75.0 mL/h adiponitrile, 370 mL/h NH₃ and 200 mL/h H passed through the reactors at 250 bar to give 100.0% adiponitrile conversion with 0.9% selectivity for 6-aminocapronitrile and 98.9% selectivity for H₂N(CH₂)₆NH₂.

AB The present invention is directed to a one-step method for forming a supported catalyst complex of high activity by substantially simultaneously contacting a bidentate or tridentate ligand forming compound, a transition metal compound and a chromium immobilized Lewis acid support-agglomerate. A typical catalyst was manufactured by mixing Na silicate with H₂SO₄ 8 min, washing the resulting gel with 2% NH₃ solution 18-36 h at 65.5°, washing the base-washed gel with water at 82°, milling the washed gel as a 20% aqueous slurry until the colloidal content was 20-25%, mixing the resulting wet-milled material with a 20% aqueous slurry of dry-milled, base-water-washed gel prepared by flash or spray drying the base-water-washed gel to moisture content <10% and milling to average particle size 5 µm in a 25:75 wet-milled material-dry-milled material ratio, combining the resulting slurry with a montmorillonite (I) slurry at silica-I ratio 80:20, mixing the resulting slurry with 1% aqueous Cr(OAc)₃ solution, spray drying, activating by heating with air in fluidized bed at 400°/h to 540°, contacting 3 g activated support with 80 mg each bis(2,6-diisopropylaniline-1,8-naphthylene) and NiBr₂(1,2-dimethoxyethane).

AB 6-Aminocapronitrile and hexamethylenediamine are simultaneously prepared by:
 (A) the hydrogenation of adiponitrile (I) in the presence of a transition metal-containing catalyst to produce a mixture of 6-aminocapronitrile (II), hexamethylenediamine, and high-boiling components; (B) separating the hexamethylenediamine from the step A mixture by distillation; (C)

distillatively

separating out the 6-aminocapronitrile; (D) distillatively separating out the adiponitrile; and (E) simultaneously distillatively separating out the I and II from the obtained fractions from step C. Steps D and E are conducted at bottom temps. under 185°; process flow diagrams are presented.

AB The emission control device contains a catalytic mineral metal alloy (predominantly containing a plagioclase feldspar belonging to the albite-anorthite series and containing small amts. of mica, kaolinite and serpentine, and optionally magnetite) capable of reducing pollutants in the combustion gases generated from an internal combustion engine, as well as from other combusted solid and liquid fossil fuels such as coal, and is also useful for treating combustion gases generated from the incineration of landfill garbage and tire rubber, among others. The catalytic material of the present invention is highly resistant to deactivation or poisoning from contaminants in the combusted material such as leaded gasoline.

AB H₂S and/or COS are removed from gases containing ≤2 volume% O₂ by active C containing (1) a Cu compound and (2) an alkali metal compound and/or alkaline earthmetal compound at ≤150°. Thus, active C 16-24 mesh with a surface area of 1040 m²/g was saturated with a solution containing Cu(NO₃)₂ and KNO₃.The 50 mL product was packed into a quartz-glass column and calcined 30. min in flowing N₂ at 350°. The resulting adsorbent contained 2.0 mmol Cu and 1.0 mmol K. Then, a gas containing N₂ 97.5, H₂O 2.5 weight%, and

COS

12.5 ppm was passed at 40 cm/s through the catalyst (15 mL) in a glass column 1.6 cm diameter at 40°. The COS removal after 25, 50, 75, and 100 h was 100, 100, 99, and 90%, resp.

AB Catalysts with improved selectivity for the title process, having average pore diameter (p) $\leq 10,000$ nm, average particle diameter (d) ≤ 5 mm, and $p/d > 2.0 + 10^{-6}$, are prepared by impregnating 100 parts support with 10-75 parts Fe group metal and 1-50% promoter, drying, and calcining. Thus, passing 1:1 CO-H over a catalyst containing Fe 25, Cu 1.25, K 1, and SiO₂ parts (p 20 nm, d 2.2 mm) at 250°/30 bar and space velocity 1000 volume/h gives 75 g hydrocarbon/g catalyst-h and selectivity (% of hydrocarbons containing >2 C) 78, compared with 75 and 69, resp., for a similar catalyst with p 2.4 nm and d 2.2 mm.

ABSTRACT:

Selective synthesis of light olefins (ethylene, propylene) from synthesis gas was studied utilizing various zeolite-based catalysts. (1) New metal/zeolite catalyst: The catalyst was synthesized hydrothermally from zeolite and Fe(II or III) compounds such as Fe₃O₄, Fe₂O₃, FeOOH. Figure 1 shows scanning electron micrographs of Fe₃O₄ and the Fe₃O₄/ZSM-5 catalyst. No Fe₃O₄ particle was observed in the latter. Figure 2(b) shows an X-ray diffraction diagram of this catalyst. The reflections of ZSM-5 and Fe₂O₃ were observed. Appearance of the diffraction peaks in Fe₂O₃ are attributed to oxidation of Fe₃O₄ in this catalyst by calcination in air. Figure 3 illustrates X-ray photoelectron spectra of the catalyst before and after grinding. The catalyst before grinding had very weak peaks of iron. By grinding the catalyst, these peaks became very strong, while the silicon peaks did not substantially change. From these results, it is concluded that the Fe₃O₄/ZSM-5 catalyst thus obtained has a unique texture in which Fe₃O₄ particles are enveloped with ZSM-5 zeolite. The results of conversion of synthesis gas over various metal/zeolite catalysts are given in Table 1. (2) Zeolite-based iron catalyst: The ***catalyst*** was prepared using FeSO₄ and Fe(NO₃)₃ as a source of iron in the same method described above. The synthetic zeolite-based iron ***catalyst*** had a well defined crystalline ZSM-5 structure. Figure 5 shows the results of conversion of synthesis gas over the catalysts. The catalysts prepared from an Fe(II) compound were more active than those prepared from an Fe(III) compound. The (C₂H₄+C₃H₆) selectivity of the former was lower than that of the latter. In order to elucidate these differences involving the activity and the selectivity, X-ray diffraction patterns of various catalysts were measured. In the case of the catalysts prepared from the Fe(III) compound, the d(084)-spacing sharply increased with the Fe/Si atomic ratio. (abridged author abst.)

STATUS: New

ABSTRACT:

Selective synthesis of gasoline from syngas was investigated using composite ***catalysts*** of iron-based mixed metal-oxides and a shape-selective aluminosilicate, H-ZSM-5, and a chromosilicate. Addition of Mn component to an Fe/H-ZSM-5 evidently improved the C2-C4 olefin selectivity, although the increase of CO conversion was rather small. Combination of Ru with the Fe-Mn/H-ZSM-5 by two-stage supporting method increased the space-time conversion of CO to hydrocarbons. When the Fe-Mn-Ru components were supported on Γ -alumina instead of H-ZSM-5, C2-C4 olefins increased significantly because the Γ -alumina had little activity for the conversion of lower olefins formed. When after the Fe-Mn-Ru/ Γ -alumina, H-ZSM-5 was packed in series, the C2;C4 olefins formed through the first stage catalyst were converted almost thoroughly. However, in addition to the gasoline, C3 and C4 paraffins were also formed by the in-series catalystbeds. Therefore, instead of H-ZSM-5, a chromosilicate having a pentasil pore-opening structure the same as ZSM-5 but having a weaker acidity was used at a higher temperature and a pressure. Consequently, a high gasoline selectivity (ca. 60%) was achieved, as the hydrogenation of C2-C4 olefins to corresponding paraffins had been avoided. (author abst.)

ABSTRACT: Two series of Mn- or Fe-promoted zirconia samples were prepared: (i) a series of sulfate-free reference compounds via co-precipitation of aqueous solutions containing **zirconium** and the **promoter** cation and (ii) a series of catalysts via incipient wetness impregnation of a sulfated **zirconium** hydroxide. The **promoter** content was varied between 0 and 5 wt% metal. All promoter-containing materials were calcined at 923 K. The reference materials contained mainly isolated Mn or Fe species incorporated into the zirconia lattice as evidenced by stabilization of the tetragonal zirconia phase, EPR (isolated ions in highly symmetric environment), and a shrinking unit cell volume (XRD) of the tetragonal zirconia phase with increasing promoter content. Only the Mn-promoted catalysts showed such shrinkage in unit cell volume with increasing promoter content. At 2 wt% promoter content, Fe could and Mn could not be detected by ion scattering spectroscopy on the surface of the catalysts. The **Fe-promoted catalysts** contained Fe₂O₃-like surface species (EPR, XANES), which could at least in part be removed by washing with oxalic acid. Catalysts were tested for isomerization at 338 K using 1 kPa n-butane in balance of N₂. At 0.5 wt% promoter content the maximum rates produced by the 0.5 wt% Mn- and Fe-promoted sulfated zirconia were about 80 and 20 $\mu\text{mol g}^{-1}\text{h}^{-1}$, respectively. Mn was thus more effective as a promoter for n-butane isomerization than Fe, despite the more extensive incorporation into the zirconia lattice.

ABSTRACT: The catalytic dehydrogenation of ethylbenzene to
produce styrene is an important industrial process
because it is used in the manufacture of resins,
synthetic rubber and plastics. The most used catalysts
for this process are iron oxides containing potassium
and chromium oxides. These catalysts show high
activity and selectivity but deactivate with time
on-stream in the industrial units, mainly due to the
loss of potassium. On the other hand, the storage of
the exhausted catalytic materials causes environmental
damage because of the toxicity of chromium compounds.
In order to find non-toxic and potassium-free
catalysts, the effect of aluminum and the salt
precursor on the properties of iron oxides was
investigated in this work. The catalysts showed high
specific area, were resistant to reduction and were
potassium-free; these features can prevent their
deactivation. Also, they showed higher activity and
selectivity than hematite and were no harmful for the
environment. In these catalysts aluminum acts both as
textural and structural promoter. Among the starting
salt precursors studied (nitrate, sulfate and
chloride), the iron chloride was the most efficient
one, producing active and selective catalysts with
high resistance against deactivation.

ABSTRACT: The high-temperature shift (HTS) reaction is an important step in industrial processes and gas purification. Although the catalyst shows a stable performance, the search for non-toxic systems is much needed, especially due to environmental restrictions related to chromium compounds. In this work, the performance of aluminum-doped catalysts with low amounts of copper was investigated, because of the role of copper on decreasing the surface area of the catalysts based on iron oxides.
Samples were prepared by precipitation methods, characterized by several techniques and evaluated under different conditions, in order to find operational conditions more effective in the use of energy. The addition of small amounts of copper to aluminum-doped hematite leads to better catalytic properties. Likely, copper behaves as a structural promoter while aluminum is a textural one. The catalyst can work at more severe conditions than the industrial condition, that is, lower steam to gas molar ratio (S/G = 0.4) and at a lower temperature (350°C). In addition, it can be easily handled and discarded without any damage to the environment or human beings.

ABSTRACT: Copyright (c) 1996 Elsevier Science B.V. All rights reserved. Zirconia-supported dehydrogenation catalysts based on **manganese** oxide and cobalt oxide were investigated. Preparation of zirconia-supported Mn(-K) and Co(-K) catalysts was carried out by (co-) impregnation of zirconia pellets to incipient wetness. Characterization of the fresh catalysts was performed using nitrogen adsorption, electron microscopy (TEM), X-ray diffraction (XRD), temperature-programmed reduction (TPR), and X-ray photoelectron spectroscopy (XPS). The dehydrogenation of 1-butene was used as a catalytic test reaction. It was shown that catalysts containing finely divided cobalt oxide or **manganese** oxide homogeneously distributed over zirconia supports can be prepared using a pre-shaped zirconia support. From the results obtained with various characterization techniques it was concluded that preparation using complex organic precursors results in the best dispersion of the active phase. The metal-EDTA complex seems the most suitable for producing the desired catalyst systems. Catalysts without **potassium** carbonate deactivate due to carbon deposition. The deactivation behaviour of supported cobalt oxide is similar to that of supported iron oxide, while supported **manganese** oxide shows a more gradual deactivation. The Mn- or Co-based catalysts containing **potassium** carbonate did not show deactivation up to at least 10 h on stream. The activity and selectivity are different, however. The activity ranking was found to be Fe,K > Mn,K > Co,K. The selectivity of the **manganese** oxide-based system was found to be higher than in the iron oxide-based catalyst.

ABSTRACT: Performances of supported transition-metal oxide catalysts in the catalytic reduction of SO₂ with CO as a reducing agent were investigated. According to the study, Fe₂O₃/γ-Al₂O₃ was found to be the most active catalyst among eight γ-Al₂O₃-supported catalysts tested. With Fe₂O₃ as the active species, CeO₂ is the most suitable support. Using Fe₂O₃/CeO₂, the best catalyst, the optimal feed ratio of CO/SO₂ is 3:1 and provides the highest yield of elemental sulfur and a higher conversion of SO₂. The catalyst presulfided by CO+SO₂ exhibits a higher performance than those pretreated with CO, H₂, or He. The desorption patterns of CO temperature-programmed desorption (TPD) indicate that Fe₂O₃/CeO₂ is more easily reduced by CO than Fe₂O₃/γ-Al₂O₃, while the SO₂-TPD patterns reveal that Fe₂O₃/γ-Al₂O₃, which is more seriously inhibited by SO₂ than Fe₂O₃/CeO₂, adsorbs more strongly a larger amount of SO₂. These two facts might be the predominant reasons why Fe₂O₃/CeO₂ has a far higher activity and stability.

ABSTRACT: Fe.sup.3.sup.+-, Cr.sup.3.sup.+-, Cu.sup.2.sup.+-, Mn.sup.2.sup.+-, Co.sup.2.sup.+-, and Ni.sup.2.sup.+/-exchanged Al.sub.2O3-pillared interlayer clay (PILC) or TiO2-PILC catalysts are investigated for the selective catalytic reduction (SCR) of nitric oxide by ammonia in the presence of excess oxygen. Fe.sup.3.sup.+/-exchanged pillared clay is found to be the most active. The catalytic activity of Fe-TiO2-PILC could be further improved by the addition of a small amount of cerium ions or cerium oxide. H2O and SO2 increase both the activity and the product selectivity to N2. The maximum activity on the Ce-Fe-TiO2-PILC is more than 3 times as active as that on a **vanadium** catalyst. Moreover, compared to the V2O5-WO3/TiO2 catalyst, the Fe-TiO2-PILC catalysts show higher N2/N2O product selectivities and substantially lower activities (by ~85%) for SO2 oxidation to SO3 under the same reaction conditions. A 100-hr run in the presence of H2O and SO2 for the CeO2/Fe-TiO2-PILC catalyst showed no decrease in activity.

 ABSTRACT: Uniform, ultrafine, microcrystalline, hard, pyroxenic
 glass-ceramic materials have been obtained
 successfully from basalt rock; instead of adding
 nucleation catalysts, the FeO:Fe
 .sub.20.sub.3, CaO:Na.sub.20, and CaO:MgO ratios have
 been rectified. This process has been accomplished by
 deliberately adding the smallest permissible amounts
 of oxidizers, limestone, dolomite, and soda ash (as
 additives) that are necessary to fulfill the
 monominerality requirements; these requirements affect
 the melting, workability, crystallization, and
 microstructure of the glass-ceramics. The melting
 temperature decreases as the ratios decrease (beyond
 certain limits); in addition, the workability,
 crystallization, and microstructure also improve as
 the ratios decrease. An almost-stable solid solution
 of augite or aegirine-augite composition is the only
 crystalline phase that is formed. The minimal
 FeO:Fe.sub.20.sub.3 ratio and the likelihood of a
 greater affinity of the Na.sup.+ cation for the
 Fe.sub.3.sup.+ cation, rather than the Al.sub.3.sup.+
 cation, may be responsible for increasing the
 stability and widening of the crystallization field of

the complex **aluminum**-bearing pyroxene solid solution.

ABSTRACT: The open literature concerning chemical and mechanistic aspects of the selective catalytic reduction of NO by ammonia (SCR process) on metal oxide catalysts is reviewed. Catalytic systems based on supported V.sub.2O.sub.5 (including the industrial TiO.sub.2-supported V.sub.2O.sub.5-WO.sub.3 and/or V.sub.2O.sub.5-MoO.sub.3 catalysts) and **catalysts** containing **Fe**.sub.2O.sub.3. CuO, MnO.sub.x and CrO.sub.x are considered. The results of spectroscopic studies of the adsorbed surface species, adsorption-desorption measurements, flow reactor and kinetic experiments are analyzed. The proposed reaction mechanisms are described and critically discussed. Points of convergence and of disagreement are underlined.

ABSTRACT:

The activity and selectivity of Raney **iron-manganese catalysts** for the production of low molecular weight olefins (C(,2)-C(,4)) from hydrogen and carbon monoxide were investigated. The Raney catalysts were prepared by extracting **aluminum** from an **iron-manganese-aluminum** alloy with different reagents including **sodium** hydroxide, **potassium** hydroxide, **lithium** hydroxide and ammonium hydroxide.

The data on the extent of **aluminum** extraction indicated that **sodium** hydroxide was the most effective leaching reagent. The ratios of iron to **manganese** remained constant in the catalysts regardless of the leaching agent used, while the **aluminum** content of the catalysts was found to be dependent on the degree of leaching.

The **sodium** hydroxide and **potassium** hydroxide leached catalysts chemisorbed greater amounts of hydrogen and carbon monoxide. The **sodium** hydroxide and **lithium** hydroxide leached catalysts were more selective for low molecular weight olefins. The activity of the **potassium** hydroxide leached catalyst was similar to that of the **sodium** hydroxide leached catalyst.

(alpha)-iron and magnetite (Fe(,3)O(,4)) were found in the **sodium** hydroxide leached catalyst, while a mixed phase comprised of (alpha)-iron, magnetite and FeAl(,3) was identified in the other catalysts by X-ray diffraction study. The presence of an (alpha)-iron phase was identified in all the reduced catalysts. Except for the **sodium** hydroxide leached catalyst, FeAl(,3) was also identified in all the reduced catalysts. The predominant carbide phase in the spent **potassium** hydroxide leached catalyst was (chi)-Fe(,5)C(,2) while the predominant carbide phase in the other spent catalysts was (epsilon)-Fe(,2.2)C.

Surface iron was determined to be present as an iron oxide phase after leaching, and as an iron metal phase after reduction by ESCA (Electron Spectroscopy for Chemical

Analysis). The **manganese** was found to be in the oxide state during all stages in the life of the catalysts. The spent catalyst surface was found to be almost completely covered by carbon for the **sodium** hydroxide leached, **potassium** hydroxide leached and coprecipitated catalysts, while relatively smaller portions of the catalyst surface were covered by carbon for the spent **lithium** hydroxide leached and ammonium hydroxide leached catalysts. The results suggest that surface iron atoms, and not the **manganese** atoms, were the active centers.

ABSTRACT:

The Raney Fe and Raney **Fe-Mn catalysts** were prepared by leaching the **aluminum** from Al-Fe (50/50 weight percent, wt %) and Al-Fe-Mn (59/38/3 wt %) alloys with an aqueous solution of **sodium** hydroxide (2 to 20 wt %) in the temperature range of 298 to 363 K by two different leaching modes, caustic or alloy addition.

The major phase in all the Raney Fe and Raney **Fe-Mn catalysts** was found to be (alpha)-Fe from X-ray diffraction study. The BET surface area of the Raney **Fe catalyst** ranged from 26 to 54 m²/g, while it ranged from 64 to 116 m²/g for Raney **Fe-Mn catalysts** depending on the preparation conditions. The crystallite size of the (alpha)-Fe in the Raney catalysts, estimated by X-ray line broadening, ranged from 70 to 250 (ANGSTROM) and it increased with increasing leaching temperature.

The optimum reduction temperature was found to be 648 K for the Raney **catalysts (Fe and Fe-Mn)** and 673 K for the precipitated **catalysts (Fe and Fe-Mn)** from thermogravimetric analyses. The Raney and precipitated catalysts, reduced in-situ in flowing hydrogen, were evaluated for the hydrogenation of carbon monoxide in a high-pressure fixed-bed reactor at the following standard reaction conditions: pressure = 1465 KPa, space velocity = 3.0 cm³g⁻¹s⁻¹, H₂/CO = 2.0, and reaction temperature of 423 to 473 K.

The Raney Fe and Raney **Fe-Mn catalysts** were 2 to 4 times more active in terms of carbon monoxide conversion than the corresponding precipitated Fe and **Fe-Mn catalysts**, respectively, at the standard reaction conditions. The

activation energy ranged from 96 to 139 KJ/mol depending on different catalysts. The C(,2)-C(,4) hydrocarbon yields for the Raney Fe and the Raney Fe-Mn catalysts were similar, ranging from 34 to 40 percent at 453 K. However, the Raney Fe-Mn catalysts showed higher C(,2)-C(,4) olefin selectivity than the Raney Fe catalysts. The same trend was found for the precipitated Fe and coprecipitated Fe-Mn catalysts. Less than 7 wt % Mn in the coprecipitated Fe-Mn and in the Raney Fe-Mn catalysts increased the olefin selectivity of the catalyst by a factor of about two.

ABSTRACT:

Addition of sodium, aluminum or manganese to alumina-supported iron catalysts can influence hydrocarbon distributions produced by hydrogenation of carbon monoxide. Combinations of sodium (Na/Fe equals 0.1) with either aluminum (Al/Fe equals 0.9) or manganese (Mn/Fe equals 0.4) produce stable catalysts with high selectivity for light olefins and concurrent suppression of methane selectivity. These effects are probably due to influences on both the dispersion of iron the support, and electronic promotion. Ratios of olefin/paraffin equals 10 were observed in the range C3-C5, with methane selectivity reduced to less than 10%. (Author abstract) 27 refs.

ABSTRACT: The behaviour of doubly promoted iron
catalysts utilized for ammonia synthesis is
modelled by the coadsorption of aluminum oxide and
potassium on iron single crystal surfaces that were
employed in high pressure reaction rate studies. The
promoter effect of aluminum oxide is
due to its interaction with iron oxide during the
preparation stage of the industrial catalyst. After
reduction, aluminum oxide stabilizes the most active
Fe(111) and Fe(211) crystal surfaces. Potassium does
not appear to be involved in the structural promotion
but its presence on the active iron surfaces increases
the rate of dinitrogen dissociation mostly by lowering
the concentration of adsorbed ammonia, thus making
more catalytic sites available for dinitrogen
dissociation. Co-adsorbed potassium and alumina form a
potassium aluminate compound that a) inhibits the
aluminum oxide induced restructuring of iron and b)
covers up the active iron sites for ammonia
synthesis. (Author abstract) 9 refs.

ABSTRACT: The general and fundamental reason for the change in
the exponent, m, and the rate constant, k, in the
Temkin equation for the ammonia synthesis reaction is
the change in the maximum heat of chemisorption of
nitrogen, q degree N_2 , and the change in the degree
of surface coverage by nitrogen this causes. The value
of q degree N_2 , and consequently m and k, may vary
because of the chemical nature of the metal as well as
because of a change in the dispersivity of the
metal. the chief role of the promoters,
additions of aluminum oxide and alkali,
consists of creating and maintaining that dispersivity
of the iron for which q degree N_2 is approximately the
optimum. (Edited author abstract) 10 refs.

ABSTRACT:

PURPOSE: To decompose and remove ammonia efficiently by causing a carrier to bear the active species of an oxide of a specific element and a group of nitrate as an ammonia decomposing agent.

CONSTITUTION: A carrier of an oxide of **titanium** or **aluminum** and zeolite is caused to bear an active species selected from among oxides group Ib elements such as Cu and Ag of the periodic table, group IIb, elements such as Zn, group IIIa elements such as La, Ce, group IIIb elements such as Al, Ca, group IVa elements such as Ti, Zr group IVb elements such as Ge, Sn group Va elements such as V, Nb, group VIa elements such as Cr, Mo group VIIa elements such as Mn, or group VIII elements such as Fe, Co, Ni, and a nitrate group of **manganese** nitrate or **iron** nitrate. The **catalyst** thus obtained demonstrates a high activity in the decomposition of ammonia, because the selective reduction reaction of NOX is generated by ammonia by deposition of an NOX source on the catalyst.

ABSTRACT:

PURPOSE: To reduce the diffusion of grain boundary and thus prevent the intrusion of iron chromium to a catalyst layer by providing the catalyst layer containing the catalyst components of precious metal on an iron support containing chromium, at least either of which has a crystal particle size of 250~500μm;

CONSTITUTION: A catalytic layer containing the catalytic component of precious metal is deposited on an iron support containing chromium, at least either of which has a crystal particle size of 250~500μm; thereby forming a catalyst for cleaning exhaust gas. It is preferable that at least an element of **vanadium**, **manganese**, **titanium** and niobium more chemically affinitive for carbon and nitrogen in the exhaust gas than iron and chromium be added to the

iron catalyst support containing chromium in the total amount of 0.1∼0.5wt.%. It is more preferable to provide an intrusion prevention layer between the support and the catalyst layer to prevent the diffusion of the iron and chromium into the catalyst layer.

ABSTRACT:

PURPOSE: To obtain high-purity silicon carbide whisker having long fibers and high aspect ratio, by reacting a silicon-containing molded article containing a specific amount of silicon dioxide with powdery carbon raw material in a hydrogen gas atmosphere under heating.

CONSTITUTION: A silicon-containing molded article containing $\geq 90\text{wt}\%$ or $\leq 60\text{wt}\%$ silicon dioxide is heat-treated with powdery carbon raw material (carbon black) in a hydrogen gas atmosphere. The hydrogen gas atmosphere contains \geq about 20vol% hydrogen and the rest of a nonoxidizing inert gas and the heating is carried out at $\geq 1,400^\circ\text{C}$ for about 30min \sim 10hr. The heat treatment is carried out in the presence of both a catalyst (iron, nickel, etc.) and a reaction promoter (sodium chloride, etc.). After silicon carbide whisker is formed by the heat treatment, the unreacted carbon raw material is further burnt at about $600\sim 1,100^\circ\text{C}$ to give straight whisker free from flex is obtained in high yield and in high productivity.

ABSTRACT:

PROBLEM TO BE SOLVED: To provide a method for producing an orthoalkylated hydroxyaromatic compound by bringing a hydroxyaromatic compound into contact with an alkyl alcohol by using a fluidized bed in a vapor phase; and to provide an alkylation catalyst for the production method, having excellent resistance to breakage and abrasion resistance, and simultaneously having good activity and selectivity, and a long life.
SOLUTION: The method for producing the orthoalkylated hydroxyaromatic compound involves carrying out a vapor-phase catalytic reaction of the hydroxyaromatic compound with the alkyl alcohol in the presence of a metal oxide catalyst by using the fluidized bed. The metal oxide catalyst contains iron, vanadium, manganese, magnesium or chromium as a metal component, and has 2-20 m²/g surface area and 0.5-2 g/ml bulk density.

LANGUAGE: Czech
ABSTRACT: An ion exchange method is described for recovery of platinum and rhenium from alumina-supported catalysts containing iron and titanium promoters. The deactivated catalyst is oxidized and treated with acid to give a solution containing the metals as chlorides: these are separated on a single ion exchange column.

ABSTRACT: The synthesis of light olefins was studied at 1 MPa on iron-manganese, -magnesium, -copper-zinc oxide-potassium oxide, and -titanium-zinc oxide-potassium oxide. The highest yield was obtained with a 20:80 iron-manganese catalyst and the highest selectivity with a 100:20:10:8 iron-copper-zinc oxide-potassium oxide. Catalyst activity and selectivity in relation to pressure, temperature, and catalyst load were examined.

LANGUAGE: English
ABSTRACT IN GERMAN: Zugabe von Mn, Ti oder Zr (unter den
Reaktionsbedingungen als Oxid) zu Rh/SiO₂-
Trägerkatalysatoren erhöht die katalytische
Aktivität für die Reaktion von CO mit H₂ um das
10-50fache unter Beibehaltung der Selektivität für
verschiedene oxydierte C₂-Verbindungen. Zugabe von Fe
führt dagegen zu einem größeren Methanolanteil und
der Bildung von Methanol ohne starke Änderung der
Aktivität. In den IR-Spektren von chemisorbiertem CO
an Rh/SiO₂-Katalysatoren mit den oxophilen Ionen von
Mn, Ti oder Zr sind die Streckschwingungsfrequenzen
ungewöhnlich stark reduziert. Demnach wird der
Kohlenstoff des CO an Rh gebunden und zugleich der
Sauerstoff an das elektropositive Metallion oder eine
Sauerstoffleerstelle (ähnlich Lewis-Säureaddukten).
Dadurch wird die Aktivierungsenergie für die
CO-Dissoziation verringert. Dagegen wird die
verbrückte CO-Chemisorption geometrisch durch
Rh-Fe-Legierungsbildung an der Rh-Oberfläche bei
Fe-Zugabe verhindert. (Weckend)

ABSTRACT:

Slurry phase Fischer-Tropsch synthesis was conducted with an ultrafine ***iron*** oxide catalyst promoted with either 0.5 at% K or 1.0 at% Zr or both. Pretreatment in CO yielded higher conversions and a more stable catalyst than activation in hydrogen or synthesis gas. Hydrogen pretreatment of K promoted catalysts and synthesis gas activation in general were less effective. Mossbauer spectroscopy and XRD showed chi-Fe₅C₂ and epsilon'-Fe₂C were formed during pretreatment in CO and did not depend on promoters present. Catalysts pretreated in H₂ were reduced to metallic Fe and Fe₃O₄; promotion with K and Zr decreased the extent of reduction. Hydrogen pretreated catalysts, promoted with K, lost surface area and carbided rapidly under synthesis conditions. Activation in synthesis gas reduced all catalysts to Fe₃O₄. Subsequent synthesis did not affect the phase present for the unpromoted and Zr promoted catalysts while those promoted with K formed chi-Fe₅C₂ and epsilon'-Fe₂C. It is concluded that pretreatment type is more important to the catalyst activity during the early period of synthesis than the impact of promotion with K and/or Zr and that changes in the bulk composition of iron catalysts do not necessarily correlate with changes in activity.

BASIC ABSTRACT:

US2005127325 A UPAB: 20050707
 NOVELTY - A sulfur removal composition comprises a metal oxide; a silica-containing material; a gallium-containing material; an **aluminum**-containing material from alumina and/or aluminate; and a

promoter metal. A portion of the **promoter** metal is present as a reduced valence **promoter** metal.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for:

(A) a method for the production of a sulfur-removal composition of the invention; and

(B) a process for the removal of sulfur from a hydrocarbon stream.

The composition is produced by a step selected from incorporating a gallium-containing substance into or onto a first calcined mixture, or incorporating a gallium-containing substance and a **promoter** metal simultaneously into or onto a second calcined mixture. The first calcined mixture comprises a liquid, a metal-containing compound, a silica-containing material, alumina, and a **promoter** metal, to form a first incorporated mixture. The second calcined mixture comprises a liquid, a metal-containing compound, silica-containing material, and alumina, to form a second incorporated mixture. The first incorporated mixture or the second incorporated mixture is dried to form a dried incorporated mixture. The dried incorporated mixture is calcined to form a calcined incorporated mixture. The calcined incorporated mixture is reduced with a suitable reducing agent under suitable conditions to produce a composition having a reduced valence **promoter** content. The composition is recovered. Removal of sulfur from a hydrocarbon stream comprising:

(1) contacting the hydrocarbon stream with the above specified sulfur removal composition;

(2) separating the desulfurized hydrocarbon stream from the sulfurized composition to form a separated desulfurized hydrocarbon stream and a separated sulfurized composition;

(3) regenerating a portion of the separated sulfurized composition in a regeneration zone to remove a portion of the sulfur contained in the composition and/or thus forming a regenerated composition;

(4) reducing the regenerated composition in an activation zone to provide a reduced composition having a reduced valence **promoter** metal content which will effect the removal of sulfur from a hydrocarbon stream when contacted with same; and

(5) returning a portion of the reduced composition to the desulfurization zone.

USE - For the removal of sulfur from hydrocarbon stream comprising fuel from cracked-gasoline and/or diesel fuel (claimed).

ADVANTAGE - The sulfur removal composition has sufficient attrition resistance that removes sulfur from hydrocarbon streams and that can be used in fluidized, transport, moving, or fixed bed reactors. It can be produced in an economical manner.

BASIC ABSTRACT:

EP 1547685 A UPAB: 20050823

NOVELTY - A catalyst for converting hydrogen or hydrocarbon liquids or gases to produce heat is prepared using a fibrous carrier of aluminum of silicon, e.g. with a density of less than 4 g/cm³, and applying an aqueous solution of a metal salt with an organic solvent promoter. Prior to application the solution is magnetically polarized to improve solubility. The material is then dried at 40 to 300 deg. C, preferably 100 to 200 deg. C.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a catalytic heater containing a pre-heating arrangement (5) and a catalyst of this type. The housing (4) is open on one side and has an inlet (7) for a gas or liquid, preferably supplied at a pressure of less than 5 mbar.

USE - Catalyst for producing heat from hydrogen or hydrocarbons without a flame, e.g. for hot water heating (claimed), space heating (claimed), heating air production (claimed), lacquer drying (claimed), heating articles in shaping plastics or rubber (claimed), disposal of exhaust gases (claimed).

ADVANTAGE - Absence of an open flame extends range of application. Radiation wavelength can be influenced by supply pressure and catalyst density.

DESCRIPTION OF DRAWING(S) - The drawing shows a schematic view of a heater.

NOVELTY - A nickel and/or cobalt coated sponge catalyst comprises sponge support having surface, and metal consisting of nickel and/or cobalt coated on portion of the surface of the support.

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a method of preparing nickel and/or cobalt plated sponge catalyst comprises preparing an aqueous slurry containing sponge support having surface area; adding to the slurry a salt of metal consisting of nickel and/or cobalt to deposit the metal on portion of the surface area of the support and to form a plating slurry containing ions of metal; adding a reducing agent to the plating slurry to deposit the metal ions in the slurry to corresponding metal; adjusting pH and temperature of plating slurry to deposit the metal on surface of the support and form metal coated sponge catalyst; and removing the catalyst from the plating slurry.

USE - Used in preparation of organic compounds, and in removal of sulfur, nitrogen, and phosphorous containing compounds and heavy metals from petroleum feedstock (claimed).

ADVANTAGE - The invention has activity and/or selectivity comparable to conventional nickel and/or cobalt sponge catalyst, but require reduced content of nickel and/or cobalt.

BASIC ABSTRACT:

US2004122115 A UPAB: 20040716

NOVELTY - A Fischer-Tropsch catalyst comprises iron; silver; optionally, **manganese** and/or zinc; first promoter(s) from sodium, lithium, potassium, rubidium, and/or cesium; optionally; second promoter(s) from calcium, magnesium, boron, and/or **aluminum**; and structural promoter(s).

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are included for:

(a) a method of making a Fischer-Tropsch catalyst, comprising precipitating **iron** compound(s), optionally silver compound(s), optionally **manganese** compound(s) and optionally zinc compound(s) from a suitable solution and under suitable conditions to provide a precipitate; optionally, washing the precipitate to provide a clean precipitate; adding first promoter compound(s) to a slurry comprising the clean precipitate; optionally, adding second promoter compound(s) to a slurry comprising the clean precipitate; adding structural promoter compound(s) to the slurry comprising the clean precipitate to provide a precursor slurry; spray-drying the precursor slurry to provide catalyst precursor particles; calcining the catalyst precursor particles under suitable conditions to provide a calcined

pre-catalyst; optionally, impregnating the calcined pre-catalyst with a compound comprising silver, sodium, lithium, potassium, rubidium and/or cesium to provide the catalyst; drying the catalyst under suitable conditions to provide a dry catalyst; calcining the dry catalyst under suitable conditions to provide the catalyst; and optionally, reducing the catalyst under conditions suitable for providing the reduced catalyst; and

(b) a process of producing hydrocarbons, comprising contacting a reactant gas mixture comprising synthesis gas with the Fischer-Tropsch catalyst under suitable conditions and in a suitable reactor.

USE - For a slurry bubble column reactor or a fixed bed reactor.
(Claimed)

ADVANTAGE - The inventive catalyst has a low water-gas shift activity, and high selectivity and productivity toward a hydrocarbon wax.

BASIC ABSTRACT:

US2004102642 A UPAB: 20040723

NOVELTY - An iron promoted **vanadium** antimony oxide catalyst is made by using an iron containing compound having Brunauer-Emmett-Teller (BET) surface area of greater than 120 m²/g. It has an atomic ratio of iron to **vanadium** of greater than 0.2.

USE - For making an iron promoted **vanadium** antimony oxide catalyst useful in the ammoxidation of propane to acrylonitrile (claimed). The catalyst is also useful in processes for the ammoxidation of 3-5C paraffinic hydrocarbon to its corresponding alpha - beta -unsaturated nitrile, the ammoxidation of propylene with ammonia (NH₃) and oxygen to acrylonitrile, the ammoxidation of methylpyridine with NH₃ and oxygen to make cyanopyridine, the ammoxidation of m-xylene with NH₃ and oxygen to make isophthalonitrile, or the oxidation of o-xylene to make phthalic anhydride.

ADVANTAGE - The inventive method can produce iron promoted **vanadium** antimony oxide catalyst having superior activity and performance.

BASIC ABSTRACT:

WO2004000456 A UPAB: 20040128

NOVELTY - A liquid mixture of a catalyst support or its precursor, metal-containing compound(s) (where the metal is **vanadium**, chromium, **manganese**, iron, cobalt nickel, copper, molybdenum or tungsten) and polar organic compound(s), is prepared. The mixture is converted to solid residue, which is then combusted in oxygen-containing atmosphere to partially convert organic compound to carbon and to form supported catalyst or its precursor.

DETAILED DESCRIPTION - A liquid mixture of a catalyst support or its precursor, metal-containing compound(s) (where metal is chosen from **vanadium**, chromium, **manganese**, iron, cobalt nickel, copper, molybdenum and tungsten) and polar organic compound(s) which acts as solvent for metal-containing compound, is prepared. The prepared liquid mixture contains 0-20 weight% of water. The mixture is then converted to paste or solid residue, which is then combusted in an oxygen-containing atmosphere to partially convert organic compound to carbon and to form supported catalyst or catalyst precursor.

INDEPENDENT CLAIMS are also included for the following:

(1) Fischer-Tropsch synthesis, hydrotreating, hydrocarbon partial oxidation, steam reforming or carbon dioxide reforming reaction, using supported catalyst or its precursor;

(2) a Fischer-Tropsch synthesis catalyst or its precursor; and

(3) a steam-reforming catalyst or its precursor.

USE - Used for preparing a supported catalyst or its precursor used in Fischer-Tropsch synthesis, hydrotreating reaction (e.g. hydroisomerization reaction), hydrocarbon partial oxidation, steam reforming or carbon dioxide reforming reaction (claimed) and partial oxidation of methane (POM) for producing syngas.

ADVANTAGE - The process effectively provides a supported catalyst or catalyst precursor used in chemical reactions, including Fischer-Tropsch synthesis and steam reforming reactions.

BASIC ABSTRACT:

WO2003043734 A UPAB: 20030820
NOVELTY - An iron-based Fischer-Tropsch catalyst comprises ferrihydrite as main iron phase, and alumina as a structural promoter.
DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a process for preparing the above iron-based catalyst precursor by co-precipitating an alumina together with a main iron phase,

which is a ferrihydrite.

USE - The catalyst is used in the conversion of synthesis gas, e.g. carbon monoxide and hydrogen, to alcohols, olefins, or paraffins, by reacting the synthesis gas in the presence of the catalyst (claimed).

ADVANTAGE - The inventive catalyst has increased activity and selectivity towards alcohols and olefins, thus providing significant yield.

BASIC ABSTRACT:

RU 2199387 C UPAB: 20030505

NOVELTY - Alumina-based catalyst contains (on conversion to oxides) 2-15% chromium oxide, 2-15% copper oxide, at least one additional element selected from alkali and alkali-earth metals, **silicon**, iron, magnesium, **titanium**, **zirconium**, and cerium in amounts from 0.01 to 45% and 2 to 15% of **promoter**: at least one compound of metal from following group: magnesium, nickel, **manganese**, cobalt, iron, and **vanadium**.

DETAILED DESCRIPTION - The catalyst is prepared by: (1) chromium and copper compounds, **aluminum** hydroxide, additional compound, and **promoter** are mixed and resulting mixture is molded, dried, and calcined; (2) alumina carrier bearing and additional compound is impregnated with solution containing chromium and copper compounds and **promoter**, dried, and calcined.

USE - Oxidation catalysts.

ADVANTAGE - Enhanced catalytic activity in oxidation reactions,

especially in presence of sulfur compounds, and increased mechanical strength.

BASIC ABSTRACT:

WO 200270628 A UPAB: 20050303

NOVELTY - Fischer-Tropsch hydrocarbon stream (FTHS) portion(s) is hydrocracked or hydroisomerized for preparing hydrocarbon fuel product(s). The product stream is separated into light fraction(s), fraction(s) boiling in the kerosene or diesel boiling range and heavy fraction boiling. FTHS comprises at least 35 weight% of compounds having 30C or more. The weight ratio of compounds having 60C or more and 30C or more in the stream is at least 0.2.

DETAILED DESCRIPTION - At least a portion of the FTHS is hydrocracked or hydroisomerized (I) at a conversion per pass of at most 80 wt% of the material boiling above 370 deg. C into material boiling below 370 deg. C. The product stream obtained is separated into light fraction(s) boiling below the kerosene or diesel boiling range (KDBR), fraction(s) boiling in the KDBR and a heavy fraction boiling above the KDBR. The larger portion of the heavy fraction is hydrocracked or hydroisomerized (II) at a conversion per pass of at most 80 weight% of material boiling above 370 deg. C into material boiling below 370 deg. C. The product stream obtained is separated into light fraction(s) boiling below the KDBR, fraction(s) boiling in the KDBR and a heavy fraction boiling above the KDBR. The larger portion of the heavy fraction obtained in the hydrocracking or hydroisomerization process (II) is hydrocracked or hydroisomerized in the (I) or (II) hydrocracking process. The FTHS comprises at least 35 weight% of compounds having 30C or more based on total amount of hydrocarbons in the FTHS. The weight ratio between compounds having 60C or more and compounds having 30C or more in the stream is at least 0.2. Hydrocarbon fuel product(s) boiling in the KDBR is prepared from a stream of hydrocarbons produced in the Fischer-Tropsch process. The Fischer-Tropsch process involves converting synthesis gas converted into liquid hydrocarbon and at least a portion of hydrocarbons boiling above KDBR.

An INDEPENDENT CLAIM is included for a hydrocarbon product boiling in the KDBR obtained by the hydrocarbon fuel product preparation method.

USE - For preparing hydrocarbon fuel product(s) boiling in kerosene/diesel range.

ADVANTAGE - The middle distillate obtained has good cold flow properties. The overall conversion including carbon conversion and thermal conversion of the process is high. The hydrocarbon fuel products boils in the diesel range and in the kerosene range. The heavy FTHS containing the components boiling in KDBR improves the cold flow properties.

BASIC ABSTRACT:

WO 200132805 A UPAB: 20010620

NOVELTY - A sorbent composition comprises zinc titanate support; and metal, metal oxide or metal oxide precursor **promoter**. The metal is cobalt, nickel, iron, **manganese**, copper, molybdenum, tungsten, silver, tin, and/or **vanadium**. The **promoter** metal is in reduced valence state for removal of sulfur from stream of cracked-gasoline or diesel fuel contacted with the composition under desulfurization conditions.

DETAILED DESCRIPTION - INDEPENDENT CLAIMS are also included for;

(1) A process of producing the sorbent composition comprising impregnating a solid particulate of zinc titanate with metal, metal oxide or metal oxide precursor **promoter**; drying the resulting impregnated solid particulate composition; calcining the dried particulate composition; and reducing the calcined particulate product with a reducing agent to produce a sorbent composition; and

(2) A process for removing sulfur from a stream of cracked-gasoline or diesel fuel comprising contacting the stream with a sorbent composition; separating the resulting desulfurized fluid stream from the

sulfurized sorbent; regenerating a portion of the separated sulfurized sorbent in a regeneration zone to remove a portion of the sulfur absorbed; reducing the resulting desulfurized sorbent in an activation zone to provide a reduced valence metal promoter content; and returning a portion of the resulting desulfurized, reduced sorbent to the desulfurization zone.

USE - For removal of thiophenic sulfur compounds from fluid streams of cracked-gasolines and diesel fuels.

ADVANTAGE - The composition removes sulfur compounds without adverse effect on the olefin content of the streams. It avoids reduction of octane values of the treated stream, and results in reduction of the sulfur content of the resulting treated fluid stream.

BASIC ABSTRACT:

US 6235677 B UPAB: 20031125
NOVELTY - A Fischer-Tropsch catalyst comprises a reduced aerogel or xerogel formed from the destabilization of a colloidal mixture comprising a catalytically active metal from iron, cobalt, nickel, ruthenium and/or aluminum, and a colloidal sol of a matrix metal from cerium,

titanium, zirconium, aluminum and/or silicon.

DETAILED DESCRIPTION - A Fischer-Tropsch catalyst comprises a reduced aerogel or xerogel formed from the destabilization of a colloidal mixture comprising a catalytically active metal from iron, cobalt, nickel, ruthenium and/or aluminum, and a colloidal sol of a matrix metal from cerium, titanium, zirconium, aluminum and/or silicon. The active metal comprises greater than 0.1 mole fraction of the matrix metal and catalyst metal combined.

An INDEPENDENT CLAIM is also included for a method of preparing the Fischer-Tropsch catalyst with a catalytically active metal content of greater than 0.1 mole fraction in the final composition of the matrix metal and catalyst metal combined.

USE - For producing hydrocarbons.

ADVANTAGE - The inventive catalyst provides high 5C+ hydrocarbon selectivities to maximize the value of the hydrocarbons produced, and enhances the process economics.

BASIC ABSTRACT:

US 6114567 A UPAB: 20001205

NOVELTY - Aliphatic alpha , omega -dinitriles is partially hydrogenated in a suspension containing 5-20 weight% of the catalyst based on the amount of dinitrile in a fixed bed reactor at 30-90 deg. C with a pressure of 3-20 MPa. The suspension comprises solvent, catalyst comprising specific metal, promoter and trace component.

DETAILED DESCRIPTION - Preparation of aliphatic alpha, omega -aminonitriles involves partial hydrogenation of aliphatic alpha, omega -dinitriles with a pressure of 3-20 MPa and at 30-90 deg. C in a suspension containing:

- (a) 5-20 weight% (weight%) of catalyst based on the amount of dinitrile;
- (b) promoter (0.1-5 weight%);
- (c) 0-5 weight% of trace element based on catalyst.

The catalyst is iron (Fe), nickel (Ni), ruthenium (Ru) or rhodium (Rh). The promoter is zinc, cadmium, lead, aluminum, tin, arsenic or antimony, and a trace component is alkali metal or an alkaline earth metal. When the promoter is titanium, manganese, chromium or molybdenum the catalyst do not contain Fe, cobalt, Ru or Rh. When the catalyst comprises Ru, Rh or Ni the addition of the promoter can be neglected. The suspension comprising catalyst, promoter and trace element in aqueous solution is precipitated and extruded to form a pellet. The pellet is dried at 80-150 deg. C, calcined at 150-1000 deg. C in gaseous stream comprising air or nitrogen to form calcine product. The calcined product is passivated at 20-80 deg. C in presence of oxygen and nitrogen mixture. Subsequently the passivated product is activated in reducing atmosphere for 2-24 hours at 200-500 deg. C.

USE - For preparing alpha , omega -aminonitriles.

ADVANTAGE - The catalyst used in the process has a longer life. The selectivity of alpha , omega -aminonitriles is enhanced.

 ADDITIONAL: C07B061-00

BASIC ABSTRACT:

DE 19839338 A UPAB: 20021105

NOVELTY - In simultaneous production of 6-aminocapronitrile (ACN) and hexamethylene diamine (HMD) by (a) hydrogenation of adipodinitrile (ADN) in the presence of a catalyst based on a group VIII element and multistage distillation of the resultant mixture containing ACN, HMD, ADN and high-boiling substances (HS) to separate (b) HMD and then either (c1) ACN and (d1) ADN or (c2) simultaneously ACN and ADN in separate fractions, the sump temperature in (d1) or (c2) is below 185 deg. C.

USE - ACN is an intermediate for caprolactam, which is the starting material for nylon 6, and HMD is one of the 2 starting materials for nylon 6.6.

ADVANTAGE - In existing methods, the recycled ADN contains undesirable by-products, especially amines such as 1-amino-2-cyanocyclopentene (ACCPE) and bis-hexamethylene triamine (BHMTA), which reduce the yield. These cannot be separated from ADN by distillation, as they form (quasi)azeotropes. When recycled, ACCPE forms 2-aminomethylcyclopentylamine (AMCPA), which contaminates the HMD and is very difficult to separate. The present process avoids these drawbacks. It is simple and economical and also increases the life of the catalyst. The ADN recovered is very pure and contains very little ACCPE.

DESCRIPTION OF DRAWING(S) - The drawing shows the flow scheme using 2 distillation columns.

Reactor with fixed catalyst in sump or trickling operation or suspension catalyst R1

BASIC ABSTRACT:

WO 9949968 A UPAB: 20040728

NOVELTY - A noble metal **promoter** provide a catalyst with high selectivity and increased stability in the dehydrogenation of alkyl aromatics

DETAILED DESCRIPTION - Dehydrogenation catalyst for alkyl aromatic feed comprises:

- (a) 30-90 weight% iron compound, calculated as oxide,
- (b) 1-50 weight% alkali metal source, calculated as oxide and
- (c) 0.1-1000 ppm weight noble metal selected from elemental noble metals and/or noble metal compounds.

An INDEPENDENT CLAIM is included for the dehydrogenation of steam and alkyl aromatic feed stream using the above catalyst.

USE - For use in dehydrogenation of alkyl aromatics to alkenylaromatics.

BASIC ABSTRACT:

DE 19809687 A UPAB: 19991103

NOVELTY - **Iron-based catalyst** material containing, in addition to (a) iron and/or iron compound(s), (b) 0.001-0.3 wt% **promoter** based on 2, 3, 4 or 5 elements selected from aluminium, **silicon, zirconium, titanium and vanadium**, (c) 0-0.3 wt% alkali and/or alkaline earth metal compound and (d) 0.001-1 wt% **manganese** (all based on weight of a).

DETAILED DESCRIPTION - An INDEPENDENT CLAIM is also included for a process for the hydrogenation of alpha , omega -dinitriles in presence of this catalyst material.

USE - As catalysts for the hydrogenation of alpha , omega -dinitriles (claimed). The preferred products (aminocapronitrile and hexamethylenediamine) are used especially for the production of polyamides 6 and 6.6.

ADVANTAGE - Catalyst material with a long service life, enabling the simple, economical hydrogenation of alpha , omega -dinitriles to amino-nitriles and diamines with high yield, high selectivity and minimal amounts of unwanted by-products.

BASIC ABSTRACT:

DE 3809226 A UPAB: 19930923

High temperature combustion catalyst (A) comprises a porous carrier layer on which are deposited a catalyst component (I) and three promoters

. The first promoter is a rare-earth metal (e.g. La, Ce, Pr or Nd) or alkaline earth metal (e.g. Ba, Sr or Ca), or their oxides, the second is Mg, Si or their oxides, and the third is a heavy metal (e.g. Ni, Zr, Co, Fe or Mn) or their oxides.

(I) is pref. Pd, Pt, or Rh at at least 10 weight% on the carrier layer which is e.g. Al, Ti, Si or Zr oxides, or Al titanate, and is deposited on a refractory ceramic substrate such as cordierite, mullite, alpha-alumina, ZrO₂ or TiO₂. The first promoter is 5-20 weight% (as oxide) on the carrier and the other two are each up to 10 weight% based on (I).

USE/ADVANTAGE - (A) is useful in gas turbine combustion chambers. It has excellent ignition activity at low temperature, high activity and stability at elevated temperature and long active lifetime.

Copyright of the articles to which records in this database refer is held by the publishers listed in the PUBLISHER (PB) field (available for records published or updated in Chemical Abstracts after December 26, 1996), unless otherwise indicated in the original publications. The CA Lexicon is the copyrighted intellectual property of the American Chemical Society and is provided to assist you in searching databases on STN. Any dissemination, distribution, copying, or storing of this information, without the prior written consent of CAS, is strictly prohibited.

FILE COVERS 1907 - 12 Dec 2005 VOL 143 ISS 25
FILE LAST UPDATED: 11 Dec 2005 (20051211/ED)

Effective October 17, 2005, revised CAS Information Use Policies apply. They are available for your review at:

<http://www.cas.org/infopolicy.html>

FILE REGISTRY

Property values tagged with IC are from the ZIC/VINITI data file provided by InfoChem.

STRUCTURE FILE UPDATES: 11 DEC 2005 HIGHEST RN 869700-38-9

DICTIONARY FILE UPDATES: 11 DEC 2005 HIGHEST RN 869700-38-9

New CAS Information Use Policies, enter HELP USAGETERMS for details.

TSCA INFORMATION NOW CURRENT THROUGH JULY 14, 2005

Please note that search-term pricing does apply when conducting SmartSELECT searches.

```
*****
*
* The CA roles and document type information have been removed from *
* the IDE default display format and the ED field has been added,   *
* effective March 20, 2005. A new display format, IDERL, is now     *
* available and contains the CA role and document type information.  *
*
*****
```

Structure search iteration limits have been increased. See HELP SLIMITS for details.

REGISTRY includes numerically searchable data for experimental and predicted properties as well as tags indicating availability of experimental property data in the original document. For information on property searching in REGISTRY, refer to:

<http://www.cas.org/ONLINE/UG/regprops.html>
